FOR THE PURPOSES OF INFORMATION ONLY

NOVEL PRIMERS AND METHODS FOR THE DETECTION OF DISSEMINATED TUMOR CELLS

The present invention relates to primers that specifically hybridize to nucleic acid molecules complementary to the messenger RNA transcribed from genes encoding MAGE tumor-specific antigens or a part thereof or to a complementary strand thereof as well as to diagnostic compositions comprising said antigens. The present invention further relates to methods for detecting disseminated tumor cells employing the primers of the invention as well as methods for preparing a tumor adjuvant vaccine.

Immunotherapeutic approaches have previously been applied to patients with minimal residual disease and could reduce mortality and recurrence associated with distant metastases. Since early occult dissemination of tumor cells is already present in about half of the cancer patients, efficient treatment strategies have to be developed for eliminating residual tumor cells. Many immunocytochemical and PCR-based assays using histogenetic differentiation markers exclusively allow the detection of micrometastatic cells that worsen the prognosis after local tumorectomy without identifying antigens for adjuvant immunotherapy. Limitations of RT-PCR analyses in oncological disorders resulted in the tissue-specific rather than tumor-specific expression of marker genes. Detection of disseminated tumor cells is thus restricted to a few, certain tumor types deriving from similar histological origin. Moreover, tumor cells are only detectable in front of special tissue background, so that most published approaches depend on samples taken from mesenchymal compartments. The presence of ubiquitous transcriptional factors and minimal activation of promotor sequences in background cells may cause illegitimate transcription and reduce specificity and sensitivity due to

Accordingly, the present invention relates to a primer specifically hybridizing to a nucleic acid molecule complementary to the messenger RNA transcribed from a

characterized in the claims.

histological origins. The solution to said problem is achieved by the embodiments disseminated tumor cells in patients with malignancies of many different invention was to improve the sensitivity of the prior art methods for detecting such recurrence of cancerous growth, the technical problem underlying the present patient enables the early treatment and/or vaccination in order to prevent Since, in particular, the early reliable detection of disseminated tumor cells in a

histological origins.

disseminated tumor cells derived from human malignancies of many different disclosed in this application are not expected to be suited for the detection of disseminating MAG-3 may be employed to detect such tumors. However, methods including MAG-3 may be further described that a number of markers therefore. In said application, it is further described that a number of markers and breast cancer cells including occult cancer cells or metastatic cells derived samples. WO 96/29430 discloses genetic markers for the detection of melanomas however, inappropriate for the diagnosis of disseminated tumor cells in human The specific primers as well as the regions they prime to in the MAG-3 genes are, MAG-1 to 4, 6 and 12 for the detection of a variety of tumors (WO 95/23874). The MAG-3 genes have been employed in the prior art to use primers specific for

and;

(ii) primers that overlap with a primer sequence depicted in (a) or (b).

The term "overlap" in this context means the overlap of at least one nucleotide.

The present invention accordingly provides a means for detecting a cancerous condition at a very early stage of the disease and thus allows the timely treatment of patients where disseminated tumor cells are detected. It was surprisingly found by the present invention that, in contrast to prior art reports, disseminated tumor cells of many different histological origins can be detected using the above-recited primers, even if the analyzed patient has no clinical evidence of disease. It has to be emphasized that the prior art methods and primers as well as the regions of the MAGE genes to which the primers described in the prior art hybridize are not suitable for detecting disseminated tumor cells in samples of patients with malignancies of many different histological origins since the sensitivity of said primers has, in accordance with the present invention, proven not to be high enough for such an analysis. The term "specifically hybridizing" as used in accordance with the present invention is intended to mean that these primers do not cross-amplify nucleic acids from the genes of other MAGE tumor specific antigens in a sensitive RT-PCR. Such RT-PCRs can be devised by the person skilled in the art according to conventional protocols. The specific hybridization occurs under stringent conditions. Such conditions can be devised by the person

In accordance with the present invention, it was found that the primers having the above-recited 3' ends are particularly useful in detecting disseminated tumor cells of many different histological origins at a sensitivity level that was unknown from the prior art. Additionally, primers that overlap with the above-recited nucleic acid sequences and that hybridize to MAGE genes have been found useful for the detection of disseminated tumor cells in human samples. Preferably, said primers overlap with the nucleic acid sequences depicted under (a), above. It is further preferred that the primers of the invention have a length of between 15 and 25 nucleotides. With the exception of primers that recognize MAGE-3 and -6, each of said primers specifically detects the expression of only one MAGE gene.

Accordingly, said primers can hybridize to RNA, preferably mRNA or to DNA, preferably cDNA.

skilled in the art without undue burden according to conventional protocols; see, e.g., "Nucleic Acid Hybridization, A Practical Approach"; edited by Hames & Higgins, IRL Press, Oxford 1985.

The primers of the invention are advantageously used in PCR amplification of nucleic acid sequences derived from the desired MAGE genes or fragments thereof. The primers of the invention are devised to avoid the amplification of genomic DNA but to amplify a DNA sequence derived from the reverse transcription of messenger RNA. In this way, the PCR product can be unambiguously correlated with expressed MAGE-genes. PCR may be carried out according to conventional methods. Also, the PCR product may be detected according to protocols that are established in the art.

Preferably, the primer of the invention is a primer depicted in either group (a) or group (b), supra.

The primers of this embodiment have been particularly useful and advantageous in identifying disseminated tumor cells in samples of patients with malignancies of many different histological origins. It is also particularly preferred that primers of group (a) are used as primers for a first round of PCR amplification whereas primers of group (b) are used in a nested primer PCR amplification.

The present invention further relates to a diagnostic composition comprising at least four primers according to the invention wherein said at least four primers hybridize pair-wise to strands of opposite orientation of at least two different nucleic acid molecules wherein strands of one orientation are complementary to the messenger RNA transcribed from the genes of at least two different MAGE tumor-specific antigens.

The diagnostic composition of the invention is particularly useful for carrying out a variety of PCRs and thus for unambiguously identifying the presence of disseminated tumor cells in patients with malignancies of many different histological origins. As has been found in accordance with the present invention,

at least two different MAGE-genes from the group of MAGE-1, -2, -3, -4, -6 and -12

- (a) carrying out PCR on cDNA obtained from mRNA from one or more patient samples using at least four primers of the invention hybridizing pair-wise to strands of opposite orientation of at least two different nucleic acid molecules wherein strands of one orientation are complementary to the messenger RNA transcribed from the genes of at least two different MAGE tumor-specific antigens;
- (b) detecting resulting PCR products; and
- (c) using at least one MAGE-gene product, expression of said MAGE-gene being detected as a result of step (b) for preparing an adjuvant tumor vaccine based on MAGE-antigen-derived peptides resembling MHC-restricted T-cell-epitopes, whole MAGE-antigens or fragments thereof, MAGE-transfected host cells, DNA vaccinating strategies using MAGE-encoding nucleotide sequences or any other immunization method based on MAGE-gene products or their coding nucleotide sequences.

This embodiment of the invention relates to the direct application of the positive analysis of the presence of disseminated tumor cells in a human sample. Once said tumor cells have been detected, a suitable antidote for the further proliferation of said tumor cells eventually resulting in tumorous growth should be devised. The method of the present invention provides such an antidote. The tumor adjuvant vaccine can be prepared according to conventional protocols. In particular, it is envisaged to pulse dendritic cells isolated from the patient with peptides derived from the coding sequences of those MAGE-genes detected to be expressed by the disseminated tumor cells of this particular patient using the diagnostic composition of the present invention, these peptides being suited for binding to MHC-molecules of this patient thus resembling MHC-restricted T-cells epitopes. The peptide-pulsed dendritic cells will then be reinjected into the patient and will migrate to the T-cell zones of secondary lymphoid organs where they prime MAGE-specific T-lymphocytes thus resulting in an immune response against MAGE-positive tumor cells.

hybridize to 2 to 6 different nucleic acid molecules complementary to the said primers in a further preferred embodiment of the method of the invention, said primers

disease status. As has been found in accordance with the present invention, the nested PCR is a further safeguard for obtaining unambiguous results with regard to the patient's nested PCR.

In an additional preferred embodiment of the method of the invention, said PCR is

Oxford/Washington DC (1985)).
 Hames & Higgins (Nucleic acid hybridization: A practical approach, IRL Press, Cold Spring Harbour Laboratory Press, Cold Spring Harbour, NY (1989)) or manuals e.g. Sambrook (Molecular Cloning: A Laboratory Manual, 2nd Edition, especially represented by computer based sequence analysis and laboratory "pan-Mage primers" can be identified and tested according to the state of the art used according to the present invention (Mage-1, -2, -3/6, -4 and -12). Such mRNA of more than one Mage gene and most preferably to all the Mage genes primers for the DNA-synthesis may be identified that efficiently hybridize to the sequence homology among different members of the Mage gene family, specific complementary to one or more Mage-MRNA species. Due to the high degree of oligo-dT-priming or by specific priming using one or more oligonucleotides carried out by random hexanucleotide priming as described in Example 3 by reverse transcription of mRNA resulting in the corresponding DNA may be conveniently effected by conventional procedures.

The preparation of said mRNA and the reverse transcription thereof is

(b) reverse transcribing said mRNA.

and

(a) preparing mRNA from one or more samples removed from said patient;

by:

In a preferred embodiment of the method of the invention, said DNA is obtained

messenger RNA transcribed from the genes of MAGE tumor-specific antigens and to complementary strands thereof.

In a further preferred embodiment of the method of the invention, said MAGE tumor-specific antigens are the MAGE-1, -2, 3, -4, -6 or -12 tumor specific antigens.

Of all MAGE antigens, the above-recited antigens most often appear on tumor cells, as was found in accordance with the present invention, and are therefore particularly indicative of the risk of cancer to develop metastatic tumors.

It is further preferred in accordance with the present invention to remove samples from two different aspiration sites. As was found in accordance with the present invention, the analysis of double-sided aspiration significantly improves sensitivity. It is therefore advisable to use double-sides aspiration in the routine diagnosis of tumor cell dissemination.

In a further preferred embodiment of the method of the invention, said samples to be analyzed are bone marrow aspirates.

As has been surprisingly found in accordance with the present invention, the use of bone marrow aspirates as a source for analyzing the metastatic potential of a patient is more sensitive than using peripheral blood as suggested by the prior art.

Additionally preferred is a method wherein said mRNA preparation comprises the following steps:

- (a) immediately lysing the sample in buffer essentially completely avoiding RNA-degradation; and
- (b) optionally centrifuging the mRNA obtained in the lysate through a cushion of an RNase-inhibiting agent, preferably cesium trifluoracetate.

This embodiment of the invention is advantageous since it precludes the loss of mRNA that is, as is well known in the art, sensitive to degradation by exonucleases and therefore precludes loss of sensitivity of the assay method.

Figure 14:

Panc-Tu: pancreas; Kato: stomach, A427: lung and A431: skin) and 2 were of mesenchymal origin (HT1080, LB23- SAR). 3 hematopoietic (U937, Raji,K562) and 6 tumor cell lines derived of neuroectodermal tissue (A172, U138: glioblastoma; Mel-Juso, Mel-Mei, A375, Mz-2Mel: melanoma) were analyzed. The melanoma cell line Mz-2Mel and the sarcoma cell line LB23-SAR were gifts of Francis Brasseur (Ludwig Institute, Brussels). The study population consisted of double-sided BM aspirates of 30 patients with prostate cancer (n=60 aspirates); single-sided BM aspirates were taken from 34 patients with non-small and small lung cancer (n=34 aspirates) and 6 patients with sarcoma (n=6 aspirates). Further, we analyzed peripheral blood samples from 12 patients with prostate cancer (n=12 samples), 6 patients with sarcoma (n=6 samples) and 12 patients with malignant melanoma (n=12 samples). All patients with prostate and lung cancer were staged as free of distant overt metastases (M0). In contrast, patients with sarcoma and malignant melanoma were suffering from advanced disease or metastases in different organs. Patients were graded by histopathological examination and staged according to the TNM-classification (4th edition, 1987). To test the specificity of the MAGE PCR assays, a "negative" control group consisting of 67 non-malignant patients: 20 BM aspirates and 20 peripheral blood samples with a history of trauma, benign tumors, inflammatory diseases or healthy donors were admitted to the study; furthermore, bone marrow of 27 healthy allogeneic bone marrow donors were analyzed with regard to expression of Mage gene products. Using heparine as an anticoagulant, BM was aspirated from one or two sides of the upper iliac crest under local anesthesia in patients with prostate cancer and sarcoma while chemotherapy or under general anesthesia in patients with lung cancer prior to tumorectomy.

Example 2: Tissue sampling and preparation

To avoid degradation of the RNA, 1 ml of the native sample was immediately within seconds mixed with 5 ml nucleic acid extraction buffer (4 M guanidine isothiocyanate, 0.5% sarcosyl (N-laurylsarcosine sodium salt), 25 mM sodium

Half of total RNA was denatured for 5 min at 70°C, quickly chilled on ice and was reverse transcribed using random λ xamer primers (Boehringer Mannheim, Mannheim, Germany). The synthesis was carried out with a First-strand DNA

Example 3: Reverse-transcriptase polymerase chain reaction

PCR camover all samples were processed at a site separate from amplification preparation was also performed as described above. To minimize the potential of PCR carryover, single cells of these lines were picked with a pipette under the microscope and mixed in 1 ml peripheral blood of a healthy donor. RNA culture flasks, single cells of these lines were picked with a pipette under the sensitivity of the PCR assay, MZ-2MeI and LB23-SAR were harvested from tissue 4 minutes and dissolved in 5 μ l DEPC-treated HPLC-water. To determine the night. After centrifugation the RNA pellet was washed with 70% ethanol, dried for isopropanol, 40 μ l 3M sodium acetate, pH=5.0 and 20 μ g glycogen at -20°C over with 300 μ l chloroform. Subsequently, the RNA was precipitated with 300 μ l vortexing and centrifugation (1 min, 14,000 rpm) the upper phase was reextracted of a phenol-chloroform-isomylalcohol mixture (25:24:1, vol:vol:vol). Again after HPLC-water. Subsequently, the sample was transferred to a fresh tube with 300 μ l a bed of ice and the RNA pellet was dissolved in a total of 300 μ l DEPC-treated the tube was cut off with a scalpel. The bottom was turned over again, placed on inverted, placed on a paper towel to drain for 2 minutes, and the bottom 1 cm of solution were removed by aspiration and discarded. The tubes were quickly nucleic acid extraction buffer/BM or blood mixture and the lower layer of CsFA-centrifuged at 35,000 rpm for 18 h at 15°C. After centrifugation, the upper layer of diethyl pyrocarbonate (DEPC)-treated, autoclaved SW40 centrifuge tubes and trifluoroacetate (Pharmacia, Freiburg, Germany) and 0.25 M EDTA, pH=7.0) in The lysate was gently overlaid onto a 5 ml cushion of CsFA-solution (cesium For purifying total RNA the method of Okayama et al. was modified as follows: could easily and without risk of RNA degradation be stored at -20°C until needed. citrate, pH=7.0) and 0.7% 2-mercaptoethanol. After vigorous vortexing the sample

and electrophoresis of PCR products.

synthesis kit (Gibco, Eggenstein, Germany), including Superscript II (Gibco) in a final volume of 10 μ l containing 50 mM Tris (pH=8.3), 75 mM KCl, 3 mM MgCl₂, 10 mM DTT, 0.5 mM total dNTP, 1.6 μ g of the random primers and 100 units Superscript II. After the addition of RNA, the samples were incubated at 40°C for 1 hour and subsequently diluted with 10 μ l HPLC-water.

PCR-reaction mixture (10 μ l) was composed of 1 μ l cDNA, 1 μ l of 10xPCR buffer (100 mM Tris, pH=8.3, 500 mM KCl, 10 mM MgCl₂), 40 μ M dNTP, 0.4 μ M of each of the two primers, 5 μ g BSA (Boehringer Mannheim, Mannheim, Germany), 0.6 units of Taq DNA-Polymerase (Boehringer Mannheim, Mannheim, Germany) and overlaid with 12.5 μ l of mineral oil. The primers for the MAGE genes were designed from previously published sequences (Tab. 1, Fig.1), and were selected to maximize mismatches between the different MAGE-sequences particularly in the 3'-region in order to avoid cross-amplification. Specific PCR assays were possible for MAGE genes 1,2,4 and 12 since the percentage of identity of these genes varies between 64 to 85 %. In contrast, the sequence of Mage-6 was found to be 99% identical to that of Mage-3. Therefore our primers for Mage-3/6 hybridize to both genes and PCR can detect Mage-3 and/or Mage-6 expression. Short primers in the range of 19-22 bases and annealing temperatures of about 60°C were most efficient. Also junction primers spanning over two exons showed surprising results in efficiency. As published recently, we applied primers for PSA (Tab. 1) on exons 2 and 3 that span a 1.6-kilobase intron and amplify three different PSA cDNAs. To confirm the presence of cDNA template in each sample, primers specific for p53 (kindly provided by Thomas Blankenstein, München, Tab. 1) were used to coamplify this ubiquitously expressed "housekeeping" gene. Oligonucleotide primers were synthesized and purified at Genset, Paris. For the external fragment amplification of the MAGE PCR assays following cycling profile was used: denaturation at 94°C for 6 min, annealing at 60°C for 30 sec and extension at 72°C for 2 min for the first cycle; denaturation at 93°C for 40 sec, annealing at 60°C for 30 sec and extension at 72°C for 20 sec for 14 cycles; denaturation at 93°C for 40 sec, annealing at 60°C for 30 sec and extension at 72°C for 30 sec for 50 cycles; terminal extension at 72°C for 2 min and cooling at

Germany; these as well as all other antibodies used in the experimental part of and later obtained from Dr. H. Bodenmüller, Boehring r Mannheim, Tutzling, antibodies CK2 (kindly provided by Dr. M. Osborn, Max Planck Institut Göttingen, minutes (5×10^5 cells per slide). BM specimens were stained with monoclonal for 30 minutes, interface cells were cytocentrifuged onto glass slides at 150g for 5 centrifugation through Ficoll-Hypaque (Pharmacia, Freiburg, Germany) at 400g cells (MNC) from the remaining aspirate were isolated by density gradient After removal of 1 ml of whole BM and blood for PCR analyses, mononuclear

of the nested PCR assay was 100%.
of a malignant tumor cell line mixed with 1 ml normal whole blood. Reproducibility approach, the RT-PCR assays for the different MAGE genes could detect 10 cells amplification products obtained was monitored with DNA sequencing. Using this Germany) was used as a reference marker for all assays. The specificity of the bromide staining under UV-light. A 1 kb DNA ladder (Gibco BRL, Eggenstein, on 1.8% agarose by gel electrophoresis and by direct visualization after ethidium preparation and RT-PCR were performed routinely. PCR products were analyzed contaminate. Negative control reactions (mock reactions) for the RNA amplification were performed in different rooms to avoid potential DNA cross-laminar air-flow bench with filtered pipette tips, extremal and nested fragment using plate control. Importantly, all pipetting was performed on ice under a was performed on a Hybaid Thermal Reactor (Biometra, Göttingen, Germany) 64°C and 7 cycles with 57°C, continuing 50 cycles with 57°C. The amplification and separating the 14 cycles into 7 cycles with and annealing-temperature of min. The cycling conditions for PSA varied by using conventional one-stage PCR 72°C (30 sec) with a final extension at 72°C for 2 min and cooling at 30°C for 1 amplification thirty more cycles were run at 93°C (40 sec), 58°C (30 sec) and tube containing the PCR mixture described above. For the nested fragment 30°C for 1 min. One microliter of the reaction was then transferred into a second

the application were prepared according to conventional procedures. The specific antibodies used here are not essential for carrying out the invention) and A-45-B/B3 (kindly provided by Micromet GmbH, Martinsried, Germany), which detect common epitopes on cytokeratin components. The antibody reactions were developed with the alkaline phosphatase anti-alkaline phosphatase (AAPAAP) technique combined with the Neufuchsin method for visualizing antibody binding. Briefly, after incubation with the primary antibody, a polyvalent rabbit anti-mouse Ig antiserum (Z259, Dako, Hamburg, Germany), and performed complexes of alkaline phosphatase and monoclonal anti-alkaline phosphatase antibodies (D651, Dako, Hamburg, Germany) were used at the dilutions recommended by the manufacturer (Dakopatts, Hamburg, Germany). For each BM aspirate, two slides containing a total of 106 MNC were evaluated

Example 5: Expression of MAGE genes in normal bone marrow and blood versus other markers

RNA was extracted from BM of control patients and subjected to RT-PCR amplification using primers from several histogenetic differentiation markers and tumor-associated antigens. (Tab. 2). After 50 cycles of amplification, product of all these candidate genes known to be expressed in malignancies was seen except PSA and MAGE genes. Nevertheless, PSA expression is restricted to malignancies of the prostate and seems to be downregulated in a fraction of disseminated tumor cells. In contrast, MAGE genes are ubiquitously expressed in malignancies and no amplification product after sensitive nested PCR was seen in any of the analyzed 20 BM aspirates and 20 peripheral blood samples. This result was confirmed when analyzing bone marrow aspirates of 27 healthy persons. None of said aspirates from the allogenic bone marrow donors expressed the MAGE genes, see Table 5.

genes in both aspiration sites, while 16 patients displayed heterogeneous interestingly, only two patients showed concordant expression pattern of MAGE positivity for expression of at least one MAGE gene in one patient was 18 (60%).
pat. (17%), MAGE-4 in 6 pat. (20%) and MAGE-12 in 5 pat. (17%). The overall were observed in 12 patients (40%), MAGE-2 in 3 pat. (17%), MAGE-3/6 in 5 prostate cancer (Tab. 4a, Tab. 7). Out of the 30 patients transcribed of MAGE-1 first, BM aspirates were obtained from both sites of the iliac crest of patients with

Prostate cancer

14.

Gel electrophoresis of Mage PCR products is shown in examples in Figures 5 to origin. Results and patient characteristics are listed in Table 4a-c and Table 7. blood samples from patients suffering from malignancies of different histological hematopoietic tissue encouraged us to evaluate BM aspirates and peripheral MAGE genes together with the complete absence of expression in normal showed MAGE-2 and -4 expression. This heterogeneous expression pattern of the completely negative. Increasing the sensitivity by performing 65 cycles A498 therefore scored positive in the PCR. Only one renal cell carcinoma (A498) was with 35 cycles, 27 of 28 cell lines exhibited expression of at least one MAGE and RT-PCR assay in vitro and screened 28 cell lines of epithelial, mesenchymal, hematopoietic and neuroectodermal origin (Tab. 3). Performing one-stage PCR as shown for prostate cancer in Table 6, we initially evaluated our multilmarker show a heterogeneous expression pattern for different MAGE genes (1,2,3,4,6,12), disseminated tumor cells of different histological origin. Since primary tumors with different types of tumors

Example 6: Expression of MAGE genes in bone marrow samples of patients

The highly restricted expression pattern of tumor antigens in contrast to tumor-associated molecules strongly supports that MAGE genes may be interesting candidates for PCR-based detection of minimal residual disease.

expression. There was no correlation between the primary tumor stage, the histopathological grading or the mean PSA concentration in serum and the MAGE-positivity in the PCR-assay.

Lung cancer

The second epithelial tumor entity we were interested in was non-small and small lung cancer (Tab.4b). We analyzed single-sided BM aspirates of 34 carcinoma patients with positive results for MAGE-1 in 5 asp. (15%), MAGE-2 in 4 asp. (12%), MAGE-3/6 in 3 asp.(9%), MAGE-4 in 3 asp. (9%) and MAGE-12 in 4 asp.(12%). At least one MAGE expression was found in 12 asp. (35%). MAGE-PCR displayed positive signals in 7 of 19 BM aspirates of patients with squamous cell carcinoma and 3 of 10 analyzed BM aspirates of patients with adenocarcinoma.

Sarcoma

Since mesenchymal tumor cell lines express different MAGE genes, we analyzed single-sided BM aspirates of 6 sarcoma patients staged as M1 using the sensitive MAGE PCR assays (Tab. 4c). 5 samples showed at least expression of one MAGE gene, while MAGE 1,2,4,12 were positive in two tumor samples, respectively, and MAGE-3/6 was positive in one sample. Transcripts of all MAGE genes were found in BM aspirates of patient T.C., suffering from rhabdomyosarcoma with infiltrating bone metastases.

Example 7: Correlation of MAGE expression with other tumor cell dissemination markers

All BM aspirates of patients with malignancies of the lung and prostate were evaluated by both the MAGE RT-PCR and the well established immunocytochemical assay using mAb against cytokeratins. Expression of at least one MAGE gene and CK-status of 34 analyzed lung carcinoma samples is displayed in Fig.2. 12 aspirates showed positive results in MAGE PCR assay, while 8 aspirates revealed CK positive cells. 6 aspirates were found to be concordant positive and were all taken from patients with squamous cell

Most of recently published PCR assays claim to detect circulating tumor cells and predict high sensitivity; nevertheless the results of the analyses of PB samples taken in parallel to the BM aspiration. As listed in Table 4a, MAG-1 and MAG-3/6 transcripts were found in one patient, while MAG-4 expression could be observed in two patients with prostate cancer. Interestingly, two patients with 3/6 transcripts were found in one patient, while MAG-4 expression was completely negative for all analyzed PB samples. The obviously PCR assay was completely negative for all analyzed PB samples. The obviously lower sensitivity of the assay using peripheral blood was confirmed by analyzing patients with sarcoma (Tab. 4c). Only two patients revealed MAG-2 and 3/6 expression, while the expression of the different MAG genes in BM aspirates could not be reproduced. Further, we analyzed 12 patients with advanced and

Example 8: Expression in blood samples compared to bone marrow samples

expression as indicator for disseminated tumor cells. Comparatively, CK-immunostained cells were found only in four PSA-positive patients. Moreover, seven PSA- and CK-negative patients revealed MAG expression. Interestingly, all PSA positive patients and seven of nine CK-positive patients were confirmed by positive results of the MAG PCR assay. In 9 patients, interestingly, all PSA positive patients and seven of nine CK-positive expression was observed in 8 patients, while CK-immunostained cells were found carcinoma 18 patients showed expression for at least one MAG gene. PSA immunocytochemistry. As mentioned above, out of 30 patients with prostate carcinoma, all PSA positive patients for MAG and PSA, and of CK- shows the results of PCR assays for MAG and PSA, and of CK-CK-immunocytochemistry and a third assay: a sensitive RT-PCR for PSA. Fig. 3 further, patients with prostate carcinoma were analyzed using MAG RT-PCR, adenocarcinoma, while immunocytochemistry exhibited no CK-positive cells in carcinoma. MAG PCR showed positive results in 3 of 10 patients with this histological subtype.

metastatic malignant melanoma using the sensitive MAGE RT-PCR assay. Expression of at least one MAGE gene was observed in only 5 patients with positive results for MAGE-1,2,3/6 and 12 in two samples and MAGE-4 in one sample. The failure to detect circulating cells in patients with localized or even advanced disease seems to indicate the bone marrow as preferential indicator compartment for detecting disseminated tumor cells.

Example 9: Different expression of MAGE-genes in the primary tumor of prostate cancer patients

Total RNA was prepared primary tumors according to Chomczynski, Analytical Biochemistry 162 (1987) 156-159. Subsequently cDNA was synthesized as described in Example 6. As shown in Table 6, 7 of 20 tumors were positive for MAGE-1, 6 of 20 tumors for MAGE 2 and -12, respectively, 10 of 20 tumors for MAGE 3/6 and 4 of 20 for MAGE-4; overall, 14 of 20 tumors (70%) were positive for at least one MAGE gene product.

Example 10: Different expression of MAGE-genes in the primary tumor and in the bone marrow of the same patient as determined by the method of the invention

Total RNA was prepared from the primary tumor of sarcoma patient H. M. (see also Tab. 4c) according to Chomczynski, Analytical Biochemistry 162 (1987) 156-159. Subsequently cDNA was synthesized as described in Example 3 followed by a one-step PCR with 35 cycles for MAGE 1, 2, 3/6, 4 and 12 as described in Example 6.

MAGE-analysis of a bone marrow sample of patient H. M. was carried out according to the method of the invention. Analysis of the primary tumor (results are shown in Figure 15) revealed predominant expression of MAGE-1 and only weak and inconsistent expression of other MAGE-genes including MAGE-4 and 12. Analysis of the bone marrow, however, only revealed the expression of Mage-

analyzed, had progressive disease at the time of analysis as defined by an prostate clomy or radiation (results are shown in Fig. 4a). The remaining 8 patients neoadjuvant therapy of their primary tumor prior to curatively intended of the 30 patients, at the time of first diagnosis of prostate cancer or during data were exclusively taken from Table 7). Mage-expression was analyzed in 22 positive for both aspiration sites. For the risk analysis of prostate cancer patients SCFR, and LE-DL, respectively; in addition, patient JU-HA, turned out to be CK-left and negative results for the right bone marrow aspiration samples of patients reevaluation of the CK-immunochemistry data revealed positive results for the the time of first diagnosis of prostate cancer as given in Tab. 7. Finally, bone marrow aspiration, and therefore not identical with the initial PSA values at grading. Furthermore, the PSA values given in Tab. 4a are those at the time of data, there are some discrepancies to Table 7 with regard to tumor staging and listed as in Table 4a. However, as Table 4a contains more preliminary clinical from the right and left iliac crest, respectively. Clinical data of the patients are -3/6, -4 or -12 was detectable in at least one of two bone marrow aspirates taken regarded Mage-positive when at least one specific PCR-product for Mage-1, -2, by bone marrow analysis according to the method of the invention. Patients were in 18 of 30 prostate cancer patients disseminated tumor cells could be detected

Example 11: Risk analysis of prostate cancer patients

of the primary tumor.

tissue like bone marrow, rather than on analysis of the Mage-expression pattern analysis of the Mage-expression pattern of said cells in an appropriate indicator cells thus preventing future distant metastasis should be preferably based on the approaches according to claim 5, to eliminate systematically disseminated tumor match with that of the corresponding primary tumor. Therefore, therapeutic expression pattern of systematically disseminated tumor cells does not necessarily 4 and -12, but no expression at all of Mage-1 (Tab. 4c). Thus, the Mage-

increasing blood concentration of PSA or by a local relapse; none of these patients, however, had clinical signs of distant metastasis at the time of MAGE-analysis. As it is well established in the art, these patients have a very high risk of future distant metastasis (Zietman, Cancer Supplement 71 (1993), 959-969; Fuks, Int. J. Radiation Oncology Biol. Phys. 21 (1991), 537-547; Pound, Urol. Clin. North Am 24 (1997), 395-406); thus it would be expected that most of them have already undergone systemic dissemination of cancer cells at the time of MAGE-analysis, when clinical evident distant metastasis has not yet developed but is likely to grow out of these disseminated single tumor cells in the future. Indeed, 7 of these 8 patients (87.5%) highly at risk of distant metastasis proved to be MAGE-positive. In contrast, only 11 of 22 patients (50.0%) analyzed in temporal association with their primary tumor, and thus representing both high and low risk patients according to future distant metastasis, were found to be MAGE-positive. Interestingly, only 22.7% of the patients in the latter group (5/22) were found to be MAGE-positive for both aspiration sites, compared to 50% in the high risk group (4/8). These data indicate, that detectable MAGE-expression in at least one bone marrow sample is associated with a high risk of future distant metastasis most probably due to the presence of systemically disseminated tumor cells. Thus, a subgroup of patients suffering from cancer and especially from prostate cancer being highly at risk of future distant metastasis may be identified by the method of the invention. This subgroup may be preferentially subjected to adjuvant cancer therapy according to claim 5 or any other adjuvant approach in order to prevent the outgrowth of distant metastases from systemically disseminated single cancer cells.

Table 7-legend:

Clinical data of 30 patients with prostate cancer and the corresponding results of MAGE RT-PCR, PSA RT-PCR and CK-Immunocytochemistry as obtained by the analysis of bone marrow samples from the right and left iliac crest, respectively. Table lists: *patients*, *clinical stage* A-D, *time of first diagnosis*, *histology* (adenocarcinoma = adeno, neuroendocrine carcinoma = neuro) and corresponding *grading* (1=well differentiated, 2= moderately differentiated, 3= poorly differentiated), *TNM-stage* related to biopsy and lymphadenectomy (= b) or related to prostatectomy and lymphadenectomy (= p), *PSA-level* prior to therapy (= initial PSA), results of *immunocytochemistry and RT-PCR*, *time of aspiration* (0 = bone marrow aspiration at the time of progressive disease but without clinically evident distant metastasis, x = bone marrow aspiration at the time of first diagnosis of prostate cancer or during neoadjuvant therapy of the primary tumor prior to curatively intended prostatectomy or radiation), *treatment modality* (A = neoadjuvant antiandrogen therapy and subsequent prostatectomy, B = neoadjuvant antiandrogen therapy and subsequent radiation, C = transurethral resection, D = primary antiandrogen therapy, E = prostatectomy and adjuvant antiandrogen therapy, F = neoadjuvant antiandrogen therapy plus chemotherapy, and subsequent prostatectomy, G = prostatectomy), as well as time and result of last clinical *follow-up* (NR = no relapse, BCR = biochemical relapse as defined by continuously PSA levels over prolonged periods of time, iBCR = initially increasing PSA level over a short period of time prior to end of follow-up, LR = local relapse, DM = clinically evident distant metastasis). n.a. = not available.

 46

CLAIMS

;and

- (ii) primers that overlap with a primer sequence depicted in (a) or (b).

2. The primer according to claim 1 which is a primer depicted in either group (a) or group (b).

3. A diagnostic composition comprising at least 4 primers according to claim 1 or 2 wherein said at least four primers hybridize pair-wise to strands of opposite orientation of at least two different nucleic acid molecules wherein strands of one orientation are complementary to the mRNA transcribed from the genes of at least two different MAGE tumor-specific antigens.

4. A method of detecting disseminated tumor cells indicative of a cancerous condition in a patient comprising:

- (a) carrying out PCR on cDNA obtained from mRNA from one or more patient samples using at least two primers according to claim 1 or 2 hybridizing pair-wise to strands of opposite orientation of at least one cDNA molecule wherein strands of one orientation are complementary to the mRNA transcribed from the genes of at least one MAGE tumor-specific antigen; and
- (b) detecting one or more PCR products.

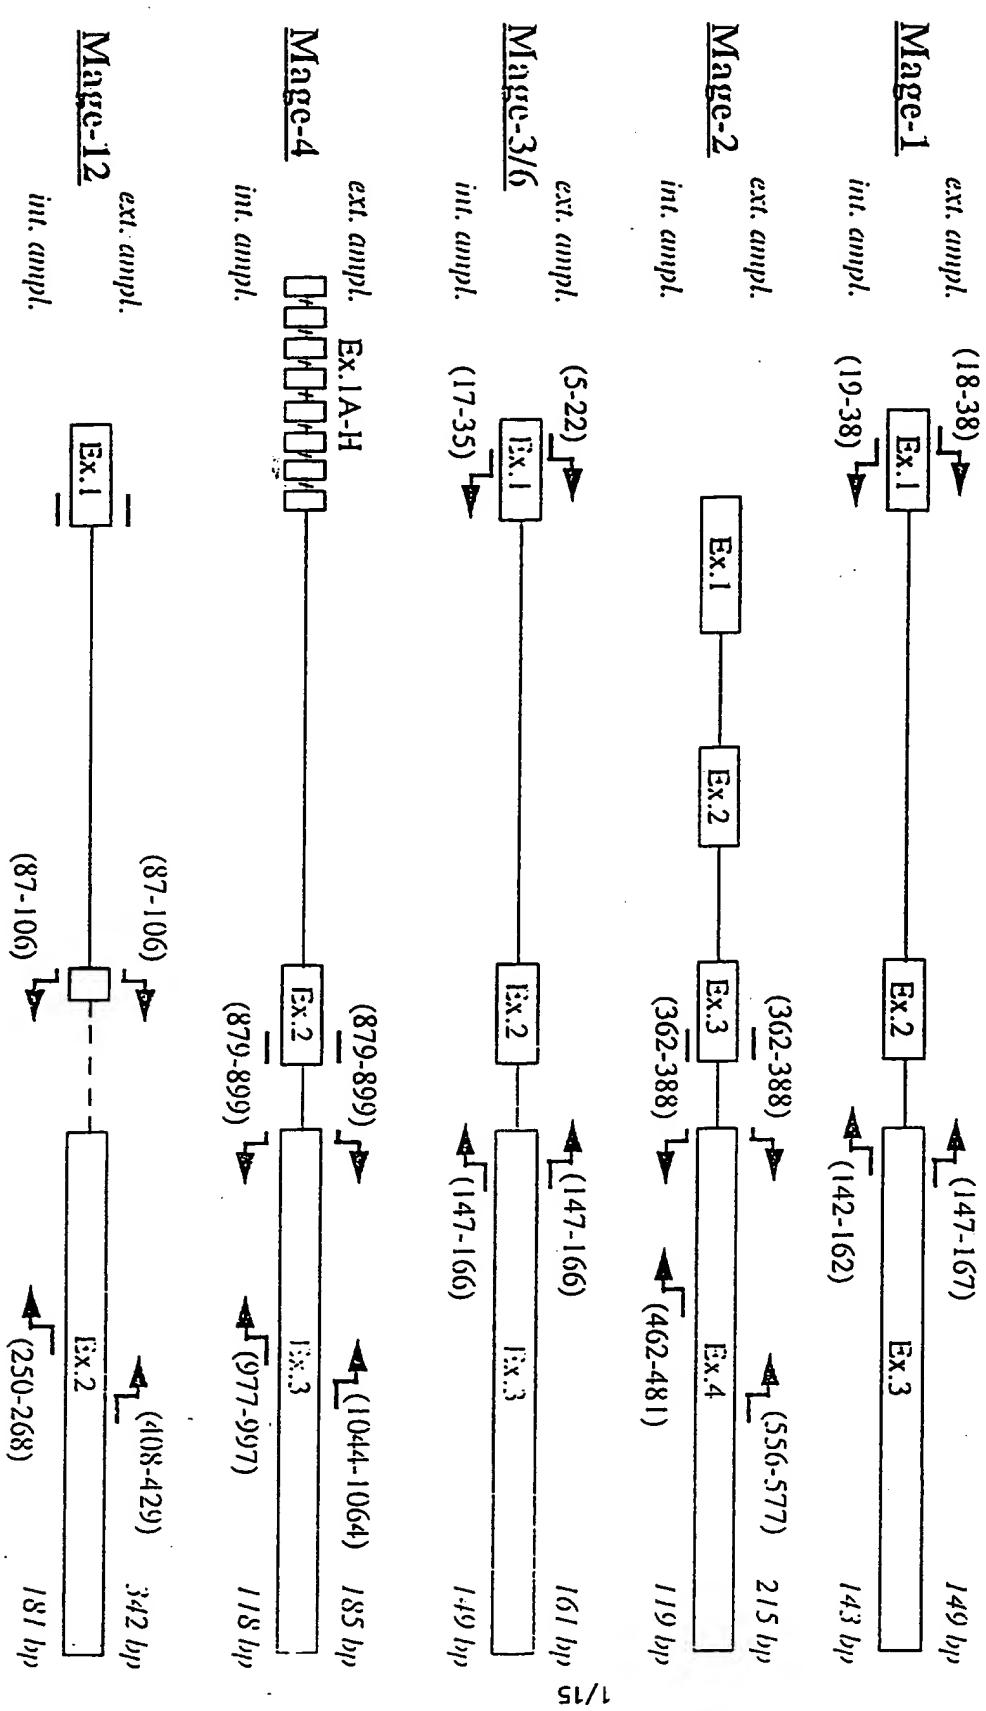

5. A method of preparing a tumor adjuvant vaccine comprising the following steps:

- (a) carrying out PCR on cDNA obtained from mRNA from one or more patient samples using at least four primers according to claim 1 or 2 hybridizing pair-wise to strands of opposite orientation of at least two different nucleic acid molecules wherein strands of one orientation are complementary to the messenger RNA transcribed

from the genes of at least two different MAGE tumor-specific genes; (b) detecting resulting PCR products; and (c) using at least one MAGE-gene product, expression of said MAGE gene being detected as a result of step (b) for preparing an adjuvant tumor vaccine based on MAGE-antigen-derived peptides recombining MHC-restricted T-cell-epitopes, whole MAGE-antigens or fragments thereof, MAGE-transfected host cells, DNA vaccinating strategies using MAGE-encoding nucleotide sequences or any other immunization method based on MAGE-sequences or any other immunization method based on MAGE-gene products or their coding nucleotide sequences. The method according to claim 4 or 5 wherein said CDNA is obtained by: (a) preparing mRNA from one or more samples removed from said patient; and (b) reverse transcribing said mRNA. The method according to any one of claims 4 to 6 wherein said PCR is nested PCR. The method according to any one of claims 4 to 7, wherein said primers hybridize to 2 to 6 different nucleic acid molecules complementary to the complementary strands thereof. The method according to any one of claims 4 to 8 wherein said MAGE tumor-specific antigens are the MAGE -1, -2, -3, -4, -6, or -12 tumor-specific antigens. The method according to any one of claims 4 to 9 wherein said samples are removed from two different aspiration sites.

11. The method according to any one of claims 4 to 10 wherein said samples are bone marrow aspirates.
12. The method according to any one of claims 4 to 11, wherein said mRNA preparation comprises the following steps:
 - (a) immediately lysing the sample in buffer essentially completely avoiding RNA-degradation; and
 - (b) optionally centrifuging the mRNA obtained in the lysate through a cushion of an RNase-inhibiting agent, preferably cesium trifluoroacetate.
13. The method according to any one of claims 4 to 12 wherein said cancerous condition is related to prostate cancer, non-small or small lung cancer, sarcoma, malignant melanoma, breast cancer or colorectal cancer.

Fig.1: Location of the specific oligonucleotide primers in the MAGE gene sequences. Grey boxes show the different exons. Arrows indicate the position of the oligonucleotides used for RT-PCR analyses. The expected size of the PCR products in the external as well as internal amplification is indicated.

2/15

(54) Title: PRIMERS AND METHODS FOR THE DETECTION OF DISSEMINATED TUMOR CELLS

(57) Abstract

The present invention relates to primers that specifically hybridize to nucleic acid molecules complementary to the messenger RNA transcribed from genes encoding MAGE tumor-specific antigens or a part thereof or to a complementary strand thereof encoding MAGE tumor-specific antigens as well as to diagnostic compositions comprising said antigens. The present invention further relates to methods for detecting disseminated tumor cells employing the primers of the invention as well as methods for preparing a tumor adjuvant vaccine.

FOR THE PURPOSES OF INFORMATION ONLY

PRIMERS AND METHODS FOR THE DETECTION OF DISSEMINATED TUMOR CELLS

The present invention relates to primers that specifically hybridize to nucleic acid molecules complementary to the messenger RNA transcribed from genes encoding MAGE tumor-specific antigens or a part thereof or to a complementary strand thereof as well as to diagnostic compositions comprising said antigens. The present invention further relates to methods for detecting disseminated tumor cells employing the primers of the invention as well as methods for preparing a tumor adjuvant vaccine.

Immunotherapeutic approaches have previously been applied to patients with minimal residual disease and could reduce mortality and recurrence associated with distant metastases. Since early occult dissemination of tumor cells is already present in about half of the cancer patients, efficient treatment strategies have to be developed for eliminating residual tumor cells. Many immunocytochemical and PCR-based assays using histogenetic differentiation markers exclusively allow the detection of micrometastatic cells that worsen the prognosis after local tumorectomy without identifying antigens for adjuvant immunotherapy. Limitations of RT-PCR analyses in oncological disorders resulted in the tissue-specific rather than tumor-specific expression of marker genes. Detection of disseminated tumor cells is thus restricted to a few, certain tumor types deriving from similar histological origin. Moreover, tumor cells are only detectable in front of special tissue background, so that most published approaches depend on samples taken from mesenchymal compartments. The presence of ubiquitous transcriptional factors and minimal activation of promotor sequences in background cells may cause illegitimate transcription and reduce specificity and sensitivity due to

Accordingly, the present invention relates to a primer specifically hybridizing to a nucleic acid molecule complementary to the messenger RNA transcribed from a histological origin. The solution to said problem is achieved by the embodiment of a disseminated tumor cells in patients with malignancies of many different involution was to improve the sensitivity of the prior art methods for detecting such recurrence of cancerous growth, the technical problem underlying the present patient enables the early treatment and/or vaccination in order to prevent Since, in particular, the early reliable detection of disseminated tumor cells in a

and;

(ii) primers that overlap with a primer sequence depicted in (a) or (b).

The term "overlap" in this context means the overlap of at least one nucleotide.

The present invention accordingly provides a means for detecting a cancerous condition at a very early stage of the disease and thus allows the timely treatment of patients where disseminated tumor cells are detected. It was surprisingly found by the present invention that, in contrast to prior art reports, disseminated tumor cells of many different histological origins can be detected using the above-recited primers, even if the analyzed patient has no clinical evidence of disease. It has to be emphasized that the prior art methods and primers as well as the regions of the MAGE genes to which the primers described in the prior art hybridize are not suitable for detecting disseminated tumor cells in samples of patients with malignancies of many different histological origins since the sensitivity of said primers has, in accordance with the present invention, proven not to be high enough for such an analysis. The term "specifically hybridizing" as used in accordance with the present invention is intended to mean that these primers do not cross-amplify nucleic acids from the genes of other MAGE tumor specific antigens in a sensitive RT-PCR. Such RT-PCRs can be devised by the person skilled in the art according to conventional protocols. The specific hybridization occurs under stringent conditions. Such conditions can be devised by the person skilled in the art according to conventional protocols.

In accordance with the present invention, it was found that the primers having the above-recited 3', ends are particularly useful in detecting disseminated tumor cells of many different histological origins at a sensitivity level that was unknown from the prior art. Additionally, primers that overlap with the above-recited nucleic acid sequences and that hybridize to MAGE genes have been found useful for the detection of disseminated tumor cells in human samples. Preferably, said primers overlap with the nucleic acid sequences depicted under (a), above. It is further preferred that the primers of the invention have a length of between 15 and 25 nucleotides. With the exception of primers that recognize MAGE-3 and -6, each of said primers specifically detects the expression of only one MAGE gene.

Accordinly, said primers can hybridize to RNA, preferably mRNA or to DNA, preferably cDNA.

skilled in the art without undue burden according to conventional protocols; see, e.g., "Nucleic Acid Hybridization, A Practical Approach"; edited by Hames & Higgins, IRL Press, Oxford 1985.

The primers of the invention are advantageously used in PCR amplification of nucleic acid sequences derived from the desired MAGE genes or fragments thereof. The primers of the invention are devised to avoid the amplification of genomic DNA but to amplify a DNA sequence derived from the reverse transcription of messenger RNA. In this way, the PCR product can be unambiguously correlated with expressed MAGE-genes. PCR may be carried out according to conventional methods. Also, the PCR product may be detected according to protocols that are established in the art.

Preferably, the primer of the invention is a primer depicted in either group (a) or group (b), supra.

The primers of this embodiment have been particularly useful and advantageous in identifying disseminated tumor cells in samples of patients with malignancies of many different histological origins. It is also particularly preferred that primers of group (a) are used as primers for a first round of PCR amplification whereas primers of group (b) are used in a nested primer PCR amplification.

The present invention further relates to a diagnostic composition comprising at least four primers according to the invention wherein said at least four primers hybridize pair-wise to strands of opposite orientation of at least two different nucleic acid molecules wherein strands of one orientation are complementary to the messenger RNA transcribed from the genes of at least two different MAGE tumor-specific antigens.

The diagnostic composition of the invention is particularly useful for carrying out a variety of PCRs and thus for unambiguously identifying the presence of disseminated tumor cells in patients with malignancies of many different histological origins. As has been found in accordance with the present invention,

adjuvant vaccine comprising the following steps:

at least two different MAGE-genes from the group of MAGE-1, -2, -3, -4, -6 and -12

- (a) carrying out PCR on cDNA obtained from mRNA from one or more patient samples using at least four primers of the invention hybridizing pair-wise to strands of opposite orientation of at least two different nucleic acid molecules wherein strands of one orientation are complementary to the messenger RNA transcribed from the genes of at least two different MAGE tumor-specific antigens;
- (b) detecting resulting PCR products; and
- (c) using at least one MAGE-gene product, expression of said MAGE-gene being detected as a result of step (b) for preparing an adjuvant tumor vaccine based on MAGE-antigen-derived peptides resembling MHC-restricted T-cell-epitopes, whole MAGE-antigens or fragments thereof, MAGE-transfected host cells, DNA vaccinating strategies using MAGE-encoding nucleotide sequences or any other immunization method based on MAGE-gene products or their coding nucleotide sequences.

This embodiment of the invention relates to the direct application of the positive analysis of the presence of disseminated tumor cells in a human sample. Once said tumor cells have been detected, a suitable antidote for the further proliferation of said tumor cells eventually resulting in tumorous growth should be devised. The method of the present invention provides such an antidote. The tumor adjuvant vaccine can be prepared according to conventional protocols. In particular, it is envisaged to pulse dendritic cells isolated from the patient with peptides derived from the coding sequences of those MAGE-genes detected to be expressed by the disseminated tumor cells of this particular patient using the diagnostic composition of the present invention, these peptides being suited for binding to MHC-molecules of this patient thus resembling MHC-restricted T-cells epitopes. The peptide-pulsed dendritic cells will then be reinjected into the patient and will migrate to the T-cell zones of secondary lymphoid organs where they prime MAGE-specific T-lymphocytes thus resulting in an immune response against MAGE-positive tumor cells.

hybridize to 2 to 6 different nucleic acid molecules complementary to the in a further preferred embodiment of the method of the invention, said primers

disease status.

further safeguard for obtaining unambiguous results with regard to the patient's As has been found in accordance with the present invention, the nested PCR is a nested PCR.

In an additional preferred embodiment of the method of the invention, said PCR is

Oxford/Washington DC (1985).

Hames & Higgins (Nucleic acid hybridization: A practical approach, IRL Press, Cold Spring Harbour Laboratory Press, Cold Spring Harbour, NY (1989)) or manuals e.g. Sambrook (Molecular Cloning: A Laboratory Manual, 2nd Edition, especially represented by computer based sequence analysis and laboratory "pan-Mage primers" can be identified and tested according to the state of the art used according to the present invention (Mage-1, -2, -3/6, -4 and -12). Such mRNA of more than one Mage gene and most preferably to all the Mage genes primers for the DNA-synthesis may be identified that efficiently hybridize to the sequence homology among different members of the Mage gene family, specific complementary to one or more MAG-E-MRNA species. Due to the high degree of oligo-dT-primering or by specific priming using one or more oligonucleotides carried out by random hexanucleotide priming as described in Example 3 by Reverse transcription of mRNA resulting in the corresponding cDNA may be conveniently effected by conventional procedures.

The preparation of said mRNA and the reverse transcription thereof is (b) reverse transcribing said mRNA.

and
(a) preparing mRNA from one or more samples removed from said patient; by:

In a preferred embodiment of the method of the invention, said cDNA is obtained

messenger RNA transcribed from the genes of MAGE tumor-specific antigens and to complementary strands thereof.

In a further preferred embodiment of the method of the invention, said MAGE tumor-specific antigens are the MAGE-1, -2, 3, -4, -6 or -12 tumor specific antigens.

Of all MAGE antigens, the above-recited antigens most often appear on tumor cells, as was found in accordance with the present invention, and are therefore particularly indicative of the risk of cancer to develop metastatic tumors.

It is further preferred in accordance with the present invention to remove samples from two different aspiration sites. As was found in accordance with the present invention, the analysis of double-sided aspiration significantly improves sensitivity. It is therefore advisable to use double-sides aspiration in the routine diagnosis of tumor cell dissemination.

In a further preferred embodiment of the method of the invention, said samples to be analyzed are bone marrow aspirates.

As has been surprisingly found in accordance with the present invention, the use of bone marrow aspirates as a source for analyzing the metastatic potential of a patient is more sensitive than using peripheral blood as suggested by the prior art.

Additionally preferred is a method wherein said mRNA preparation comprises the following steps:

- (a) immediately lysing the sample in buffer essentially completely avoiding RNA-degradation; and
- (b) optionally centrifuging the mRNA obtained in the lysate through a cushion of an RNase-inhibiting agent, preferably cesium trifluoracetate.

This embodiment of the invention is advantageous since it precludes the loss of mRNA that is, as is well known in the art, sensitive to degradation by exonucleases and therefore precludes loss of sensitivity of the assay method.

Figure 14:

Panc-Tu: pancreas; Kato: stomach, A427: lung and A431: skin) and 2 were of mesenchymal origin (HT1080, LB23- SAR). 3 hematopoietic (U937, Raji, K562) and 6 tumor cell lines derived of neuroectodermal tissue (A172, U138: glioblastoma; Mel-Juso, Mel-Mei, A375, Mz-2Mel: melanoma) were analyzed. The melanoma cell line Mz-2Mel and the sarcoma cell line LB23-SAR were gifts of Francis Brasseur (Ludwig Institute, Brussels). The study population consisted of double-sided BM aspirates of 30 patients with prostate cancer (n=60 aspirates); single-sided BM aspirates were taken from 34 patients with non-small and small lung cancer (n=34 aspirates) and 6 patients with sarcoma (n=6 aspirates). Further, we analyzed peripheral blood samples from 12 patients with prostate cancer (n=12 samples), 6 patients with sarcoma (n=6 samples) and 12 patients with malignant melanoma (n=12 samples). All patients with prostate and lung cancer were staged as free of distant overt metastases (M0). In contrast, patients with sarcoma and malignant melanoma were suffering from advanced disease or metastases in different organs. Patients were graded by histopathological examination and staged according to the TNM-classification (4th edition, 1987). To test the specificity of the MAGE PCR assays, a "negative" control group consisting of 67 non-malignant patients: 20 BM aspirates and 20 peripheral blood samples with a history of trauma, benign tumors, inflammatory diseases or healthy donors were admitted to the study; furthermore, bone marrow of 27 healthy allogeneic bone marrow donors were analyzed with regard to expression of Mage gene products. Using heparine as an anticoagulant, BM was aspirated from one or two sides of the upper iliac crest under local anesthesia in patients with prostate cancer and sarcoma while chemotherapy or under general anesthesia in patients with lung cancer prior to tumorectomy.

Example 2: Tissue sampling and preparation

To avoid degradation of the RNA, 1 ml of the native sample was immediately within seconds mixed with 5 ml nucleic acid extraction buffer (4 M guanidine isothiocyanate, 0.5% sarcosyl (N-laurylsarcosine sodium salt), 25 mM sodium

Hairt of total RNA was denatured for 5 min at 70°C, quickly chilled on ice and was reverse transcribed using random hexamer primers (Boehringer Mannheim, Mannheim, Germany). The synthesis was carried out with a First-strand DNA

Example 3: Reverse-transcriptase polymerase chain reaction

citrate, pH=7.0) and 0.7% 2-mercaptoethanol. After vigorous vortexing the sample could easily and without risk of RNA degradation be stored at -20°C until needed. For purifying total RNA the method of Okayama et al. was modified as follows: The lysate was gently overlaid onto a 5 ml cushion of CsTA-solution (cesium trifluoroacetate (Pharmacia, Freiburg, Germany) and 0.25 M EDTA, pH=7.0) in diethyl pyrocarbonate (DEPC)-treated, autoclaved SW40 centrifuge tubes and centrifuged at 35,000 rpm for 18 h at 15°C. After centrifugation, the upper layer of nucleic acid extraction buffer/BM or blood mixture and the lower layer of CsTA-solution were removed by aspiration and discarded. The tubes were quickly inverted, placed on a paper towel to drain for 2 minutes, and the bottom 1 cm of the tube was cut off with a scalpel. The bottom was turned over again, placed on a bed of ice and the RNA pellet was dissolved in a total of 300 μ l DEPC-treated HPLC-water. Subsequently, the sample was transferred to a fresh tube with 300 μ l HPLC-water. Subsequently, the sample was transferred to a fresh tube with 300 μ l of a phenol-chloroform-isomylalcohol mixture (25:24:1, vol:vol:vol). Again after vortexing and centrifugation (1 min, 14,000 rpm) the upper phase was reextracted with 300 μ l chloroform. Subsequently, the RNA was precipitated with 300 μ l isopropanol, 40 μ l 3M sodium acetate, pH=5.0 and 20 μ g glycogen at -20°C over night. After centrifugation the RNA pellet was washed with 70% ethanol, dried for 4 minutes and dissolved in 5 μ l DEPC-treated HPLC-water. To determine the sensitivity of the PCR assay, Mz-2M1 and LB23-SAR were harvested from tissue culture flasks, single cells of these lines were picked with a pipette under the microscope and mixed in 1 ml peripheral blood of a healthy donor. RNA preparation was also performed as described above. To minimize the potential of PCR carryover all samples were processed at a site separate from amplification and electrophoresis of PCR products.

synthesis kit (Gibco, Eggenstein, Germany), including Superscript II (Gibco) in a final volume of 10 μ l containing 50 mM Tris (pH=8.3), 75 mM Kcl, 3 mM MgCl₂, 10 mM DTT, 0.5 mM total dNTP, 1.6 μ g of the random primers and 100 units Superscript II. After the addition of RNA, the samples were incubated at 40°C for 1 hour and subsequently diluted with 10 μ l HPLC-water.

PCR-reaction mixture (10 μ l) was composed of 1 μ l cDNA, 1 μ l of 10xPCR buffer (100 mM Tris, pH=8.3, 500 mM KCl, 10 mM MgCl₂), 40 μ M dNTP, 0.4 μ M of each of the two primers, 5 μ g BSA (Boehringer Mannheim, Mannheim, Germany), 0.6 units of Taq DNA-Polymerase (Boehringer Mannheim, Mannheim, Germany) and overlaid with 12.5 μ l of mineral oil. The primers for the MAGE genes were designed from previously published sequences (Tab. 1, Fig.1), and were selected to maximize mismatches between the different MAGE-sequences particularly in the 3'-region in order to avoid cross-amplification. Specific PCR assays were possible for MAGE genes 1,2,4 and 12 since the percentage of identity of these genes varies between 64 to 85 %. In contrast, the sequence of Mage-6 was found to be 99% identical to that of Mage-3. Therefore our primers for Mage-3/6 hybridize to both genes and PCR can detect Mage-3 and/or Mage-6 expression. Short primers in the range of 19-22 bases and annealing temperatures of about 60°C were most efficient. Also junction primers spanning over two exons showed surprising results in efficiency. As published recently, we applied primers for PSA (Tab. 1) on exons 2 and 3 that span a 1.6-kilobase intron and amplify three different PSA cDNAs. To confirm the presence of cDNA template in each sample, primers specific for p53 (kindly provided by Thomas Blankenstein, München, Tab. 1) were used to coamplify this ubiquitously expressed "housekeeping" gene. Oligonucleotide primers were synthesized and purified at Genset, Paris. For the external fragment amplification of the MAGE PCR assays following cycling profile was used: denaturation at 94°C for 6 min, annealing at 60°C for 30 sec and extension at 72°C for 2 min for the first cycle; denaturation at 93°C for 40 sec, annealing at 60°C for 30 sec and extension at 72°C for 20 sec for 14 cycles; denaturation at 93°C for 40 sec, annealing at 60°C for 30 sec and extension at 72°C for 30 sec for 50 cycles; terminal extension at 72°C for 2 min and cooling at

After removal of 1 ml of whole BM and blood for PCR analyses, mononuclear cells (MNC) from the remaining aspirate were isolated by density gradient centrifugation through Ficoll-Hypaque (Pharmacia, Freiburg, Germany) at 400g for 30 minutes, interface cells were cytocentrifuged onto glass slides at 150g for 5 minutes (5×10^5 cells per slide). BM specimens were stained with monoclonal antibodies CK2 (kindly provided by Dr. M. Osborn, Max Planck Institut Gottingen, and later obtained from Dr. H. Bodenmuller, Boehringer Mannheim, Tutzling, Germany); these as well as all other antibodies used in the experimental part of

Example 4: Immunochemistry

30°C for 1 min. One microliter of the reaction was then transferred into a second tube containing the PCR mixture described above. For the nested fragmentation amplification thirty more cycles were run at 93°C (40 sec), 58°C (30 sec) and 72°C (30 sec) with a final extension at 72°C for 2 min and cooling at 30°C for 1 min. The cycling conditions for PSA varied by using conventional one-stage PCR and separating the 14 cycles into 7 cycles with annealing-temperature of 64°C and 7 cycles with 57°C, continuing 50 cycles with 57°C. The amplification was performed on a Hybaid Thermal Reactor (Biometra, Göttingen, Germany) using plate control. Importantly, all pipetting was performed on ice under a laminar air-flow bench with filtered pipette tips, extremal and nested fragment amplification were performed in different rooms to avoid potential DNA cross-contamination. Negative control reactions (mock reactions) for the RNA preparation and RT-PCR were performed routinely. PCR products were analyzed on 1.8% agarose by gel electrophoresis and by direct visualization after ethidium bromide staining under UV-light. A 1 kb DNA ladder (Gibco BRL, Eggenstein, Germany) was used as a reference marker for all assays. The specificity of the amplification products obtained was monitored with DNA sequencing. Using this approach, the RT-PCR assays for the different MAGe genes could detect 10 cells of a malignant tumor cell line mixed with 1 ml normal whole blood. Reproducibility of the nested PCR assay was 100%.

the application were prepared according to conventional procedures. The specific antibodies used here are not essential for carrying out the invention) and A-45-B/B3 (kindly provided by Micromet GmbH, Martinsried, Germany), which detect common epitopes on cytokeratin components. The antibody reactions were developed with the alkaline phosphatase anti-alkaline phosphatase (APAAP) technique combined with the Neufuchsin method for visualizing antibody binding. Briefly, after incubation with the primary antibody, a polyclonal rabbit anti-mouse Ig antiserum (Z259, Dako, Hamburg, Germany), and performed complexes of alkaline phosphatase and monoclonal anti-alkaline phosphatase antibodies (D651, Dako, Hamburg, Germany) were used at the dilutions recommended by the manufacturer (Dakopatts, Hamburg, Germany). For each BM aspirate, two slides containing a total of 106 MNC were evaluated

Example 5: Expression of MAGE genes in normal bone marrow and blood versus other markers

RNA was extracted from BM of control patients and subjected to RT-PCR amplification using primers from several histogenetic differentiation markers and tumor-associated antigens. (Tab. 2). After 50 cycles of amplification, product of all these candidate genes known to be expressed in malignancies was seen except PSA and MAGE genes. Nevertheless, PSA expression is restricted to malignancies of the prostate and seems to be downregulated in a fraction of disseminated tumor cells. In contrast, MAGE genes are ubiquitously expressed in malignancies and no amplification product after sensitive nested PCR was seen in any of the analyzed 20 BM aspirates and 20 peripheral blood samples. This result was confirmed when analyzing bone marrow aspirates of 27 healthy persons. None of said aspirates from the allogenic bone marrow donors expressed the MAGE genes, see Table 5.

First, BM aspirates were obtained from both sites of the iliac crest of patients with prostate cancer (Tab. 4a, Tab. 7). Out of the 30 patients transcripts of MAGE-1 were observed in 12 patients (40%), MAGE-2 in 3 pat. (17%), MAGE-3/6 in 5 patients (17%), MAGE-4 in 6 pat. (20%) and MAGE-12 in 5 pat. (17%). The overall positivity for expression of at least one MAGE gene in one patient was 18 (60%). Interestingly, only two patients showed concordant expression pattern of MAGE genes in both aspiration sites, while 16 patients displayed heterogeneous

Prostate Cancer

14.

The objective of the study was to establish a PCR assay for detection of disseminated tumor cells of different histological origin. Since primary tumors show a heterogeneous expression pattern for different MAGE genes (1,2,3,4,6,12), as shown for prostate cancer in Table 6, we initially evaluated our multimap RT-PCR assay *in vitro* and screened 28 cell lines of epithelial, mesenchymal, hematopoietic and neuroectodermal origin (Tab. 3). Performing one-stage PCR completely negative in the PCR. Only one renal cell carcinoma (A498) was therefore scored positive in the PCR. Since primary tumors with 35 cycles, 27 of 28 cell lines exhibited expression of at least one MAGE and showed MAGE-2 and -4 expression. This heterogeneous expression pattern of the MAGE genes together with the complete absence of expression in normal hematopoietic tissue encouraged us to evaluate BM aspirates and peripheral blood samples from patients suffering from malignantancies of different histological origin. Results and patient characteristics are listed in Table 4a-c and Table 7. Originally, 50 samples of Mage PCR products is shown in examples in Figures 5 to 9.

with different types of tumors

Example 6: Expression of MAGE genes in bone marrow samples of patients

The highly restricted expression pattern of tumor antigens in contrast to tumor-associated molecules strongly supports that MAGE genes may be interesting candidates for PCR-based detection of minimal residual disease.

expression. There was no correlation between the primary tumor stage, the histopathological grading or the mean PSA concentration in serum and the MAGE-positivity in the PCR-assay.

Lung cancer

The second epithelial tumor entity we were interested in was non-small and small lung cancer (Tab.4b). We analyzed single-sided BM aspirates of 34 carcinoma patients with positive results for MAGE-1 in 5 asp. (15%), MAGE-2 in 4 asp. (12%), MAGE-3/6 in 3 asp.(9%), MAGE-4 in 3 asp. (9%) and MAGE-12 in 4 asp.(12%). At least one MAGE expression was found in 12 asp. (35%). MAGE-PCR displayed positive signals in 7 of 19 BM aspirates of patients with squamous cell carcinoma and 3 of 10 analyzed BM aspirates of patients with adenocarcinoma.

Sarcoma

Since mesenchymal tumor cell lines express different MAGE genes, we analyzed single-sided BM aspirates of 6 sarcoma patients staged as M1 using the sensitive MAGE PCR assays (Tab. 4c). 5 samples showed at least expression of one MAGE gene, while MAGE 1,2,4,12 were positive in two tumor samples, respectively, and MAGE-3/6 was positive in one sample. Transcripts of all MAGE genes were found in BM aspirates of patient T.C., suffering from rhabdomyosarcoma with infiltrating bone metastases.

Example 7: Correlation of MAGE expression with other tumor cell dissemination markers

All BM aspirates of patients with malignancies of the lung and prostate were evaluated by both the MAGE RT-PCR and the well established immunocytochemical assay using mAb against cytokeratins. Expression of at least one MAGE gene and CK-status of 34 analyzed lung carcinoma samples is displayed in Fig.2. 12 aspirates showed positive results in MAGE PCR assay, while 8 aspirates revealed CK positive cells. 6 aspirates were found to be concordant positive and were all taken from patients with squamous cell

samples

Example 8: Expression in blood samples compared to bone marrow

carcinoma. MAGE PCR showed positive results in 3 of 10 patients with adenocarcinoma, while immunochemistry exhibited no CK-positive cells in this histological subtype. Further, patients with prostate carcinoma were analyzed using MAGE RT-PCR, CK-immunochemistry and a third assay: a sensitive RT-PCR for PSA. Fig. 3 shows the results of PCR assays for MAGE and PSA, and of CK-immunochemistry. As mentioned above, out of 30 patients with prostate carcinoma 18 patients showed expression for at least one MAGE gene. PSA expression was observed in 8 patients while CK-immunostained cells were found in 9 patients. Interestingly, all PSA positive patients and seven of nine CK-positive patients were confirmed by positive results of the MAGE PCR assay. Patients with CK-immunostained cells were found only in four PSA-positive patients. Moreover, seven PSA- and CK-negative patients revealed MAGE expression as indicator for disseminated tumor cells.

metastatic malignant melanoma using the sensitive MAGE RT-PCR assay. Expression of at least one MAGE gene was observed in only 5 patients with positive results for MAGE-1,2,3/6 and 12 in two samples and MAGE-4 in one sample. The failure to detect circulating cells in patients with localized or even advanced disease seems to indicate the bone marrow as preferential indicator compartment for detecting disseminated tumor cells.

Example 9: Different expression of MAGE-genes in the primary tumor of prostate cancer patients

Total RNA was prepared primary tumors according to Chomczynski, Analytical Biochemistry 162 (1987) 156-159. Subsequently cDNA was synthesized as described in Example 6. As shown in Table 6, 7 of 20 tumors were positive for MAGE-1, 6 of 20 tumors for MAGE 2 and -12, respectively, 10 of 20 tumors for MAGE 3/6 and 4 of 20 for MAGE-4; overall, 14 of 20 tumors (70%) were positive for at least one MAGE gene product.

Example 10: Different expression of MAGE-genes in the primary tumor and in the bone marrow of the same patient as determined by the method of the invention

Total RNA was prepared from the primary tumor of sarcoma patient H. M. (see also Tab. 4c) according to Chomczynski, Analytical Biochemistry 162 (1987) 156-159. Subsequently cDNA was synthesized as described in Example 3 followed by a one-step PCR with 35 cycles for MAGE 1, 2, 3/6, 4 and 12 as described in Example 6.

MAGE-analysis of a bone marrow sample of patient H. M. was carried out according to the method of the invention. Analysis of the primary tumor (results are shown in Figure 15) revealed predominant expression of MAGE-1 and only weak and inconsistent expression of other MAGE-genes including MAGE-4 and 12. Analysis of the bone marrow, however, only revealed the expression of Mage-

analyzed, had progressive disease at the time of analysis as defined by an prostatectomy or radiation (results are shown in Fig. 4a). The remaining 8 patients neoadjuvant therapy of their primary tumor prior to curatively intended of the 30 patients, at the time of first diagnosis of prostate cancer or during data were exclusively taken from Table 7). Mage-expression was analyzed in 22 positive for both aspiration sites. For the risk analysis of prostate cancer patients SCFR. and LE-DL, respectively; in addition, patient JU-HA, turned out to be CK-left and negative results for the right bone marrow aspiration samples of patients reevaluation of the CK-immunochemistry data revealed positive results for the the time of first diagnosis of prostate cancer as given in Tab. 7. Finally, bone marrow aspiration, and therefore not identical with the initial PSA values at grading. Furthermore, the PSA values given in Tab. 4a are those at the time of data, there are some discrepancies to Table 7 with regard to tumor staging and listed as in Table 4a. However, as Table 4a contains more preliminary clinical from the right and left iliac crest, respectively. Clinical data of the patients are -3/6, -4 or -12 was detectable in at least one of two bone marrow aspirates taken regarded Mage-positive when at least one specific PCR-product for Mage-1, -2, by bone marrow analysis according to the method of the invention. Patients were in 18 of 30 prostate cancer patients disseminated tumor cells could be detected

Example 11: Risk analysis of prostate cancer patients

of the primary tumor. tissue like bone marrow, rather than on analysis of the Mage-expression pattern analysis of the Mage-expression pattern of said cells in an appropriate indicator cells thus preventing future distant metastasis should be preferably based on the approaches according to claim 5, to eliminate systematically disseminated tumor match with that of the corresponding primary tumor. Therefore, therapeutic expression pattern of systematically disseminated tumor cells does not necessarily 4 and -12, but no expression at all of Mage-1 (Tab. 4c). Thus, the Mage-

increasing blood concentration of PSA or by a local relapse; none of these patients, however, had clinical signs of distant metastasis at the time of MAGE-analysis. As it is well established in the art, these patients have a very high risk of future distant metastasis (Zietman, Cancer Supplement 71 (1993), 959-969; Fuks, Int. J. Radiation Oncology Biol. Phys. 21 (1991), 537-547; Pound, Urol. Clin. North Am 24 (1997), 395-406); thus it would be expected that most of them have already undergone systemic dissemination of cancer cells at the time of MAGE-analysis, when clinical evident distant metastasis has not yet developed but is likely to grow out of these disseminated single tumor cells in the future. Indeed, 7 of these 8 patients (87,5%) highly at risk of distant metastasis proved to be MAGE-positive. In contrast, only 11 of 22 patients (50,0%) analyzed in temporal association with their primary tumor, and thus representing both high and low risk patients according to future distant metastasis, were found to be MAGE-positive. Interestingly, only 22,7% of the patients in the latter group (5/22) were found to be MAGE-positive for both aspiration sites, compared to 50% in the high risk group (4/8). These data indicate, that detectable MAGE-expression in at least one bone marrow sample is associated with a high risk of future distant metastasis most probably due to the presence of systemically disseminated tumor cells. Thus, a subgroup of patients suffering from cancer and especially from prostate cancer being highly at risk of future distant metastasis may be identified by the method of the invention. This subgroup may be preferentially subjected to adjuvant cancer therapy according to claim 5 or any other adjuvant approach in order to prevent the outgrowth of distant metastases from systemically disseminated single cancer cells.

Table 7-legend:

Clinical data of 30 patients with prostate cancer and the corresponding results of MAGE RT-PCR, PSA RT-PCR and CK-Immunocytochemistry as obtained by the analysis of bone marrow samples from the right and left iliac crest, respectively. Table lists: *patients*, *clinical stage A-D*, *time of first diagnosis*, *histology* (adenocarcinoma = adeno, neuroendocrine carcinoma = neuro) and corresponding *grading* (1=well differentiated, 2= moderately differentiated, 3= poorly differentiated), *TNM-stage* related to biopsy and lymphadenectomy (= b) or related to prostatectomy and lymphadenectomy (= p), *PSA-level* prior to therapy (= initial PSA), results of *immunocytochemistry and RT-PCR*, *time of aspiration* (0 = bone marrow aspiration at the time of progressive disease but without clinically evident distant metastasis, x = bone marrow aspiration at the time of first diagnosis of prostate cancer or during neoadjuvant therapy of the primary tumor prior to curatively intended prostatectomy or radiation), *treatment modality* (A = neoadjuvant antiandrogen therapy and subsequent prostatectomy, B = neoadjuvant antiandrogen therapy and subsequent radiation, C = transurethral resection, D = primary antiandrogen therapy, E = prostatectomy and adjuvant antiandrogen therapy, F = neoadjuvant antiandrogen therapy plus chemotherapy, and subsequent prostatectomy, G = prostatectomy), as well as time and result of last clinical *follow-up* (NR = no relapse, BCR = biochemical relapse as defined by continuously PSA levels over prolonged periods of time, iBCR = initially increasing PSA level over a short period of time prior to end of follow-up, LR = local relapse, DM = clinically evident distant metastasis). n.a. = not available.

SEQUENCE LISTING

(1) GENERAL INFORMATION:

(i) APPLICANT:

(A) NAME: Micromet GmbH
 (B) STREET: Am Klopferespitz 19
 (C) CITY: Planegg
 (D) STATE: none
 (E) COUNTRY: Germany
 (F) POSTAL CODE (ZIP): 82152

(ii) TITLE OF INVENTION: Novel primers and methods for the detection of disseminated tumor cells

(iii) NUMBER OF SEQUENCES: 20

(iv) COMPUTER READABLE FORM:

(A) MEDIUM TYPE: Floppy disk
 (B) COMPUTER: IBM PC compatible
 (C) OPERATING SYSTEM: PC-DOS/MS-DOS
 (D) SOFTWARE: PatentIn Release #1.0, Version #1.30 (EPO)

(2) INFORMATION FOR SEQ ID NO: 1:

(i) SEQUENCE CHARACTERISTICS:

(A) LENGTH: 21 base pairs
 (B) TYPE: nucleic acid
 (C) STRANDEDNESS: single
 (D) TOPOLOGY: linear

(ii) MOLECULE TYPE: other nucleic acid

(iii) DESCRIPTION:

(A) DESCRIPTION: /desc = "oligonucleotide"

(iv) MOLECULE TYPE: other nucleic acid

(a)

of primers:

(i) primers having the same 3' portion as one of the following groups strand thereof, said primer being selected from the group of a MAG-E tumor-specific antigen or a part thereof or to a complementary complementary to the messenger RNA transcribed from a gene encoding a nucleic acid molecule

CLAIMS

;and

- (ii) primers that overlap with a primer sequence depicted in (a) or (b).

2. The primer according to claim 1 which is a primer depicted in either group (a) or group (b).
3. A diagnostic composition comprising at least 4 primers according to claim 1 or 2 wherein said at least four primers hybridize pair-wise to strands of opposite orientation of at least two different nucleic acid molecules wherein strands of one orientation are complementary to the mRNA transcribed from the genes of at least two different MAGE tumor-specific antigens.
4. A method of detecting disseminated tumor cells indicative of a cancerous condition in a patient comprising:
 - (a) carrying out PCR on cDNA obtained from mRNA from one or more patient samples using at least two primers according to claim 1 or 2 hybridizing pair-wise to strands of opposite orientation of at least one cDNA molecule wherein strands of one orientation are complementary to the mRNA transcribed from the genes of at least one MAGE tumor-specific antigen; and
 - (b) detecting one or more PCR products.
5. A method of preparing a tumor adjuvant vaccine comprising the following steps:
 - (a) carrying out PCR on cDNA obtained from mRNA from one or more patient samples using at least four primers according to claim 1 or 2 hybridizing pair-wise to strands of opposite orientation of at least two different nucleic acid molecules wherein strands of one orientation are complementary to the messenger RNA transcribed

WO 98/46788

48

PCT/EP98/02081

from the genes of at least two different MAGE tumor-specific gene being detected as a result of step (b) for preparing an adjuvant tumor vaccine based on MAGE-antigen-derived peptides recombining MHC-restricted T-cell-peptides, whole MAGE-antigens or fragments thereof, MAGE-transfected host cells, DNA vaccinating strategies using MAGE-encoding nucleotide sequences or any other immunization method based on MAGE-gene products or their coding nucleotide sequences.

(c) using at least one MAGE-gene product, expression of said MAGE-gene being detected as a result of step (b) for preparing an adjuvant tumor vaccine based on MAGE-antigen-derived peptides recombining MHC-restricted T-cell-peptides, whole MAGE-antigens or fragments thereof, MAGE-transfected host cells, DNA vaccinating strategies using MAGE-encoding nucleotide sequences or any other immunization method based on MAGE-gene products or their coding nucleotide sequences.

(a) preparing RNA from one or more samples removed from said patient; and

(b) reverse transcribing said RNA.

6. The method according to claim 4 or 5 wherein said cDNA is obtained by:

(a) preparing RNA from one or more samples removed from said patient; and

(b) nested PCR.

7. The method according to any one of claims 4 to 6 wherein said PCR is

8. The method according to any one of claims 4 to 7, wherein said primers hybridize to 2 to 6 different nucleic acid molecules complementary to the complementary strands thereof.

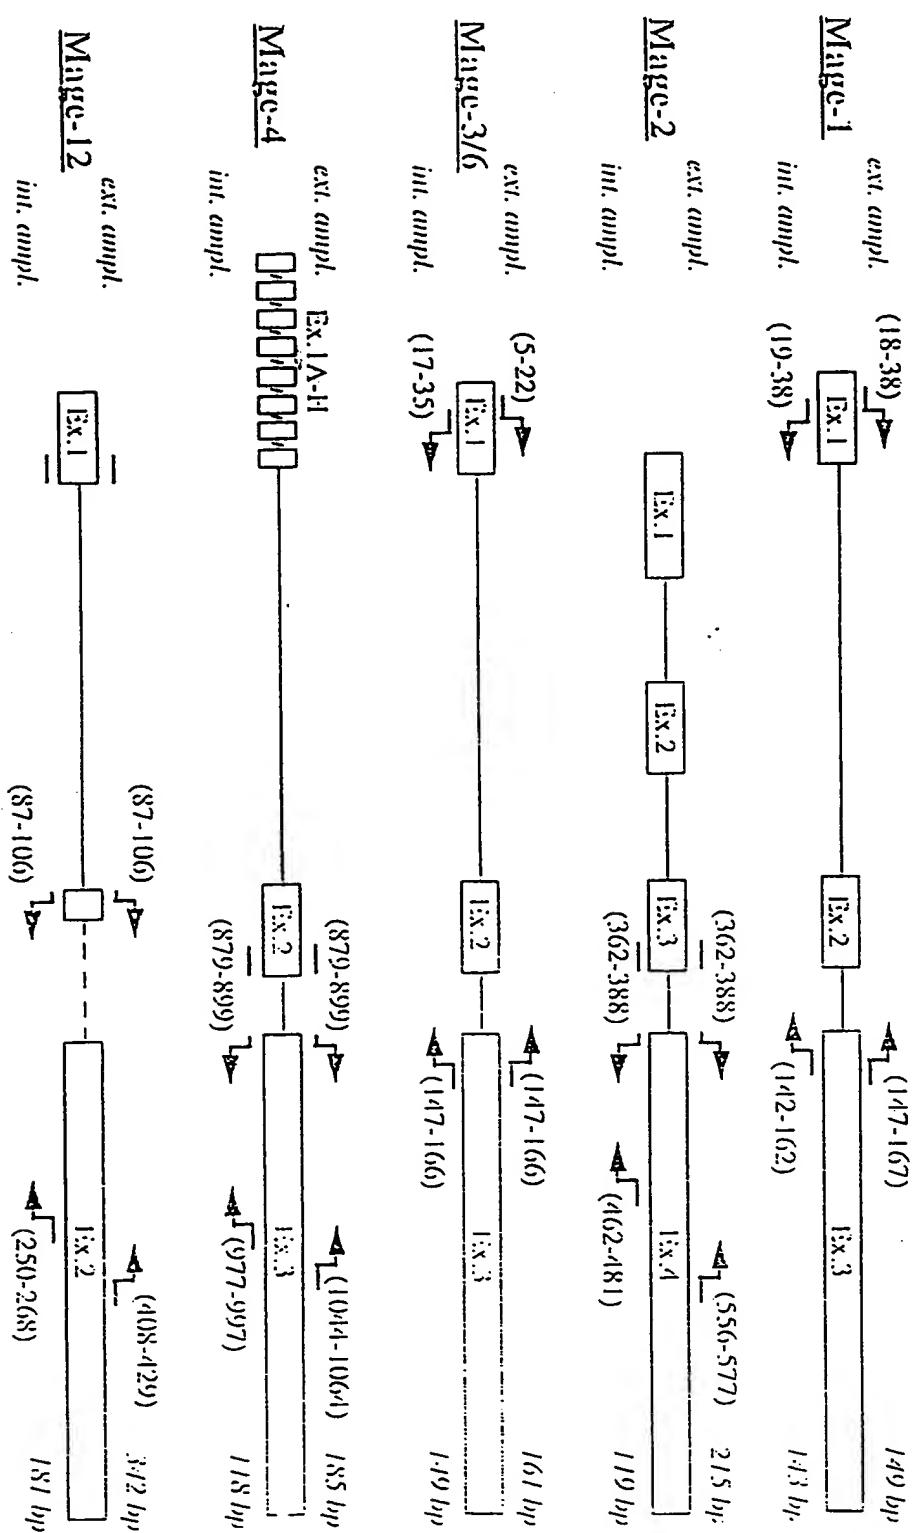

9. The method according to any one of claims 4 to 8 wherein said MAGE tumor-specific antibodies are the MAGE -1, -2, -3, -4, -6, or -12 tumor-specific antigens.

10. The method according to any one of claims 4 to 9 wherein said samples are removed from two different aspiration sites.

11. The method according to any one of claims 4 to 10 wherein said samples are bone marrow aspirates.
12. The method according to any one of claims 4 to 11, wherein said mRNA preparation comprises the following steps:
 - (a) immediately lysing the sample in buffer essentially completely avoiding RNA-degradation; and
 - (b) optionally centrifuging the mRNA obtained in the lysate through a cushion of an RNase-inhibiting agent, preferably cesium trifluoroacetate.
13. The method according to any one of claims 4 to 12 wherein said cancerous condition is related to prostate cancer, non-small or small lung cancer, sarcoma, malignant melanoma, breast cancer or colorectal cancer.

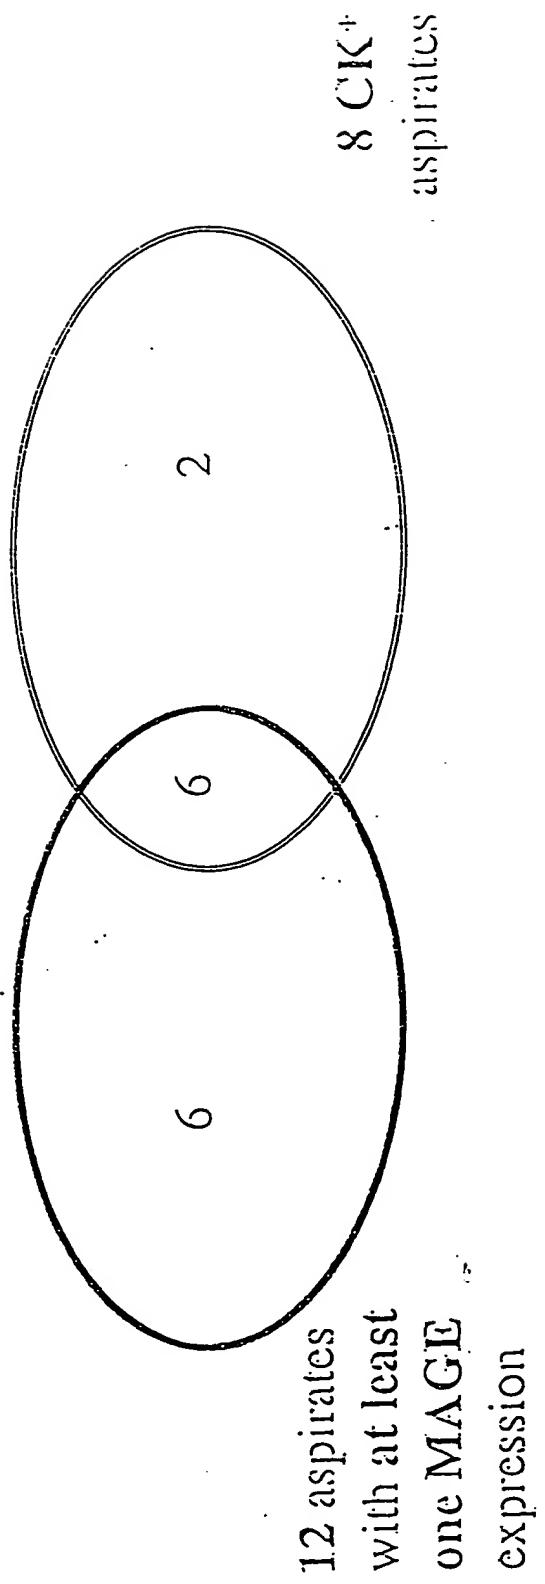

SUBSTRUCTURE SHEET (RULE 26)

Fig. 1: Location of the specific oligonucleotide primers in the MAGE gene sequences. Circled boxes show the different exons. Arrows indicate the position of the oligonucleotides used for RT-PCR analyses. The expected size of the PCR products in the external as well as internal amplification is indicated.

2/17

Fig. 2: Number of BM aspirates from lung carcinoma patients with positive results in PCR-assay for at least one MAGE and in CK-Immunocytochemistry:

A. CLASSIFICATION OF SUBJECT MATTER		IPC 6 C12Q1/68 G01N33/50
According to International Patent Classification (IPC) or to both national classification and IPC		
B. FIELDS SEARCHED		
Minimum documentation searched (classification system followed by classification symbols)		
IPC 6 C12Q 60/11		
Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched		
Electronically stored data base consulted during the international search (name of data base and where practical, search terms used)		
C. DOCUMENTS CONSIDERED TO BE RELEVANT		
Category: Classification of document, with indication, where appropriate, of the relevant passages Relevant to claim No.		
X MO 96 29430 A (WAYNE JOHN CANCER INST (US)) 26 September 1996 GENETICS INST (US) 26 September 1996 cited in the application see the whole document * see in particular page 32, line 23 and the claims *		
D. CLAIMS		
/ --		
E. FURTHER DOCUMENTS RECEIVED SINCE THE FILING DATE		
X Further documents are listed in the continuation of box C. Detailed family members are listed in annex.		
F. SPECIFIC CATEGORIES OF CITED DOCUMENTS:		
T. Letter document published after the international filing date or property date and not in conflict with the application but used to understand the principle or theory underlying the invention		
U. Document defining the general state of the art which is not considered to be of particular relevance		
V. Document of particular relevance: the claimed invention involves an inventive step which the document is taken to concern be considered novel or contains be considered to be a general principle relating to the claimed invention		
W. Document of particular relevance: the claimed invention involves an inventive step which the document is taken to concern be considered novel or contains be considered to be a general principle relating to the claimed invention		
X. Document defining the principle or theory underlying the invention		
Y. Document published prior to the claimed invention but which is cited to establish the publication date of another document or other prior art document (as specified)		
Z. Document which may throw doubt on the priority claim(s) or which is cited to establish the publication date of another document or other prior art document (as specified)		
E. FILING DATE		
X Date of the initial compilation of relevant information		
12/10/1998		
30 September 1998		
D. DATE OF MAILING ADDRESSEES OF THE ISA		
Name and mailing address of the ISA European Patent Office, P.B. 5818 Petersdorff 2 Tel. (+31-70) 340-2000, Tr. 31 651 600 nl. Fax (+31-70) 340-3016
